#	Severity	Symptom	Verdict	Evidence	Action Taken
1	High	The default settings are written to userSettings every time the page loads, before existing settings are read.	Confirmed	After changing the “dark” value to “light”, refreshing the page resets it back to its default value “dark”.	Placed the storage defaultSettings inside try/catch block
2	Medium	The code only saves the hard-coded defaults; it has no path for saving updated settings.	Confirmed	The code lacks a feature where the user can save their input when reloaded.	Updated the code so it can save user inputs and let users switch between dark and light themes.
3	Medium	localStorage .setItem() is outside the try block.	Confirmed	Having it placed outside the try/catch block means it has no safety net to fall onto.	Placed the line inside a try/catch block.
4	Medium	localStorage .getItem() is also outside the try block.	Confirmed	Having it placed outside the try/catch block means it has no safety net to fall onto.	Placed the line inside a try/catch block.
5	Medium	If the key is absent, JSON.parse () returns null; the code then accesses loadedSettings["theme"].	Confirmed	The code breaks trying to read a code with a missing “theme” key	Added a code that checks if data exists. If not, the site gives the default theme instead of breaking.
6	Low	localStorage is not encrypted by this code.	False Positive	userSettings only contains standard settings like theme, user name, and date.	No code changes were made.

7	Low	Only the "dark" theme is handled; other values do not set a correspondi ng appearance.	Confirmed	The old script only checked for dark mode. If you chose light mode, the screen stays black and you could not read the text.	Added an else structure so that if dark theme is not picked, the site loads to a default light theme with dark texts
8	Low	lastVisit is a fixed date in the source rather than a value updated on a visit.	Confirmed	The visit date stays frozen on "2026-11-01" forever instead of updating to the actual day someone loads the page.	Added a code that checks the computer's real clock so it saves the actual today's date whenever a user visits.
